

Design Engineer Takehome

The premise

An 'intelligent' notification system that surfaces helpful nudges throughout your day: reminders, suggestions, gentle nudges based on context (time of day, calendar, activity). The goal is to reduce the number of things you have to remember, without disrupting your focus.

What to build

A prototype in code, with mock data, covering:

1. **A stream/feed of notifications over a day:** some urgent, some low-priority, some purely informational
2. **Structure of a single notification:** Does it have interactions? Does this differ across notification types?
3. **Grouping/batching behavior:** what happens when multiple notifications fire at once?
4. **A "focus" or do-not-disturb mode:** what happens to notifications that would have fired while you're in focus mode?

Constraints

- Time-box: 5 hours (or less).
- A video demo of the final prototype
- (Optional) Feel free to record yourself working through this. Might be particularly helpful if there are design decisions you want to talk through!
- While you should prioritize the points mentioned above, you might end up designing for considerations that aren't listed. Maybe you feel like we missed something important or you discover something magical along the way.
- **Mock all data/timing: no real backend or scheduling needed.**

What we're evaluating

- Good judgement in design tradeoffs - **Please make decisions from the lens of Wispr!**
 - We bias towards simplicity, and prefer designs that can scale to 1b users, many of whom won't be power users 😊
- Visual taste - Ideally there are 1-2 components that you feel proud of
 - If you spend more time polishing some aspects more than others, please mention which ones we should pay more attention to!
